

1 **SUPPLEMENTAL FIGURES**  
2

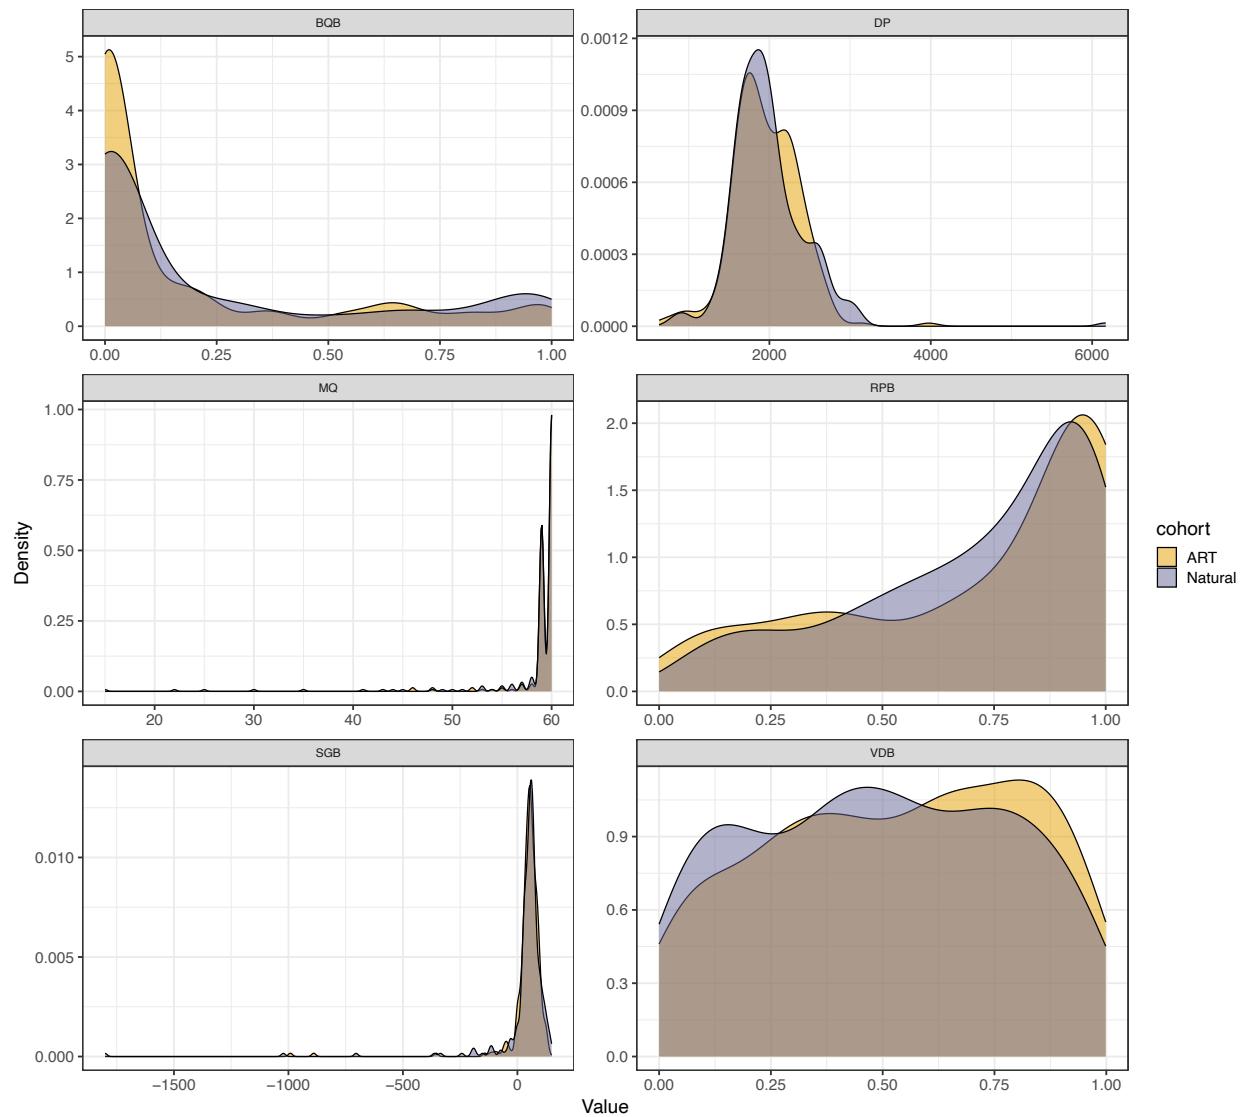

3  
4 **Supplemental Figure 1.** Base quality scores by read position and sequencing coverage for ART-  
5 (orange) and natural-born samples (purple). Two replicate paired-end 150 bp libraries were  
6 prepared from each sample and sequenced in two batches, referred to as Seq1 and Seq2.  
7 Average base quality scores across each base position in Read1 in the merged data (A) and both  
8 individual sequencing libraries (D, G). Average base quality scores across each base position in  
9 Read2 in the merged data (B) and individual Seq1 (E) and Seq2 (H) libraries. High-quality  
10 sequencing reads were obtained from both breeding cohorts in both sequencing batches,  
11 although reads from ART-derived samples have slightly lower base quality scores compared to  
12 natural-born samples in the Seq1 sequencing batch. Effective sequencing coverage for the  
13 merged, Seq1, and Seq2 data (C, F, I). Coverage estimates exclude duplicated reads and  
14 assume a genome size of 2.7Gb. Samples from both ART- and natural-born cohorts were  
15 sequenced to identical target coverage in both Seq1 and Seq2. However, a batch effect in sample  
16 preparation, library construction, and sequencing manifested as a higher rate of duplicated reads  
17 in the ART-derived samples compared to natural-born samples during Seq1 data collection (F).

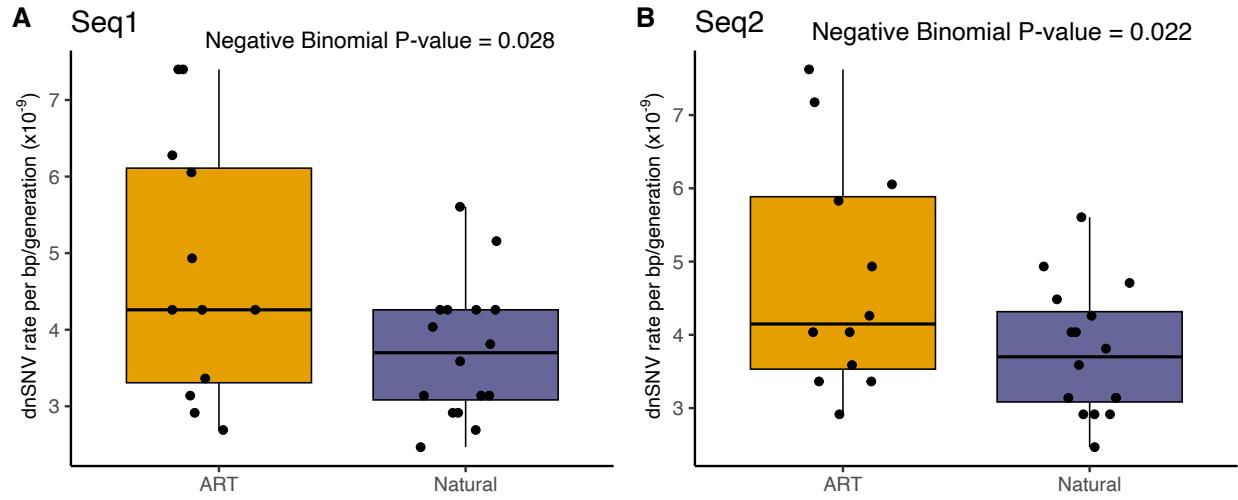

18  
 19 **Supplemental Figure 2.** Base quality scores by read position and sequencing coverage for the  
 20 G0 pedigree founder pair and G1 parents of the ART- and natural-born G2 cohorts. Two  
 21 libraries were prepared from each sample and processed in two different sequencing runs,  
 22 Seq1 and Seq2. Average base quality scores across each base position in Read1 for the  
 23 merged sequencing data (A) and individual Seq1 (D) and Seq2 (G) sequencing data. Average  
 24 base quality scores across each base position in Read2 for the merged, Seq1, and Seq2  
 25 sequencing data (B, E, H). Effective sequencing coverage for the merged, Seq1, and Seq2  
 26 sequencing data (C, F, I).

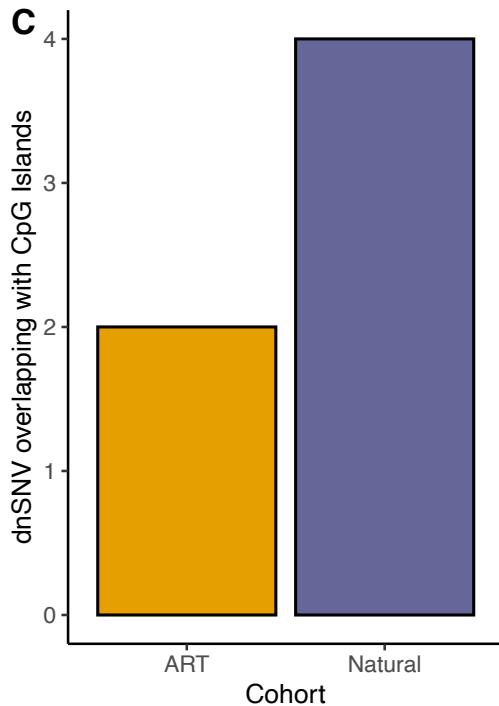

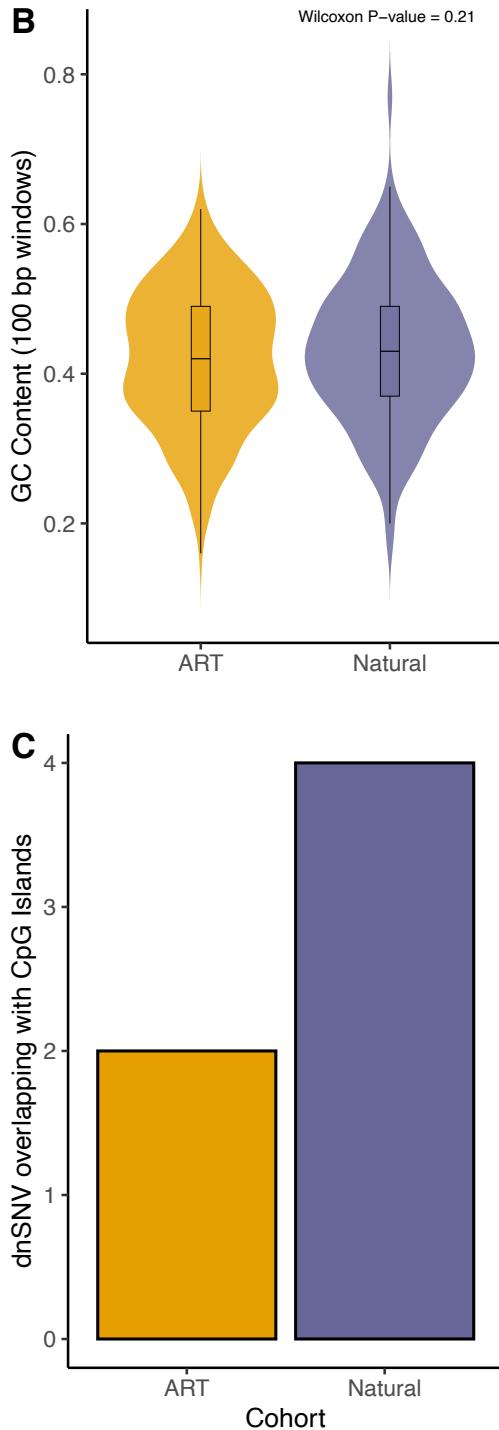

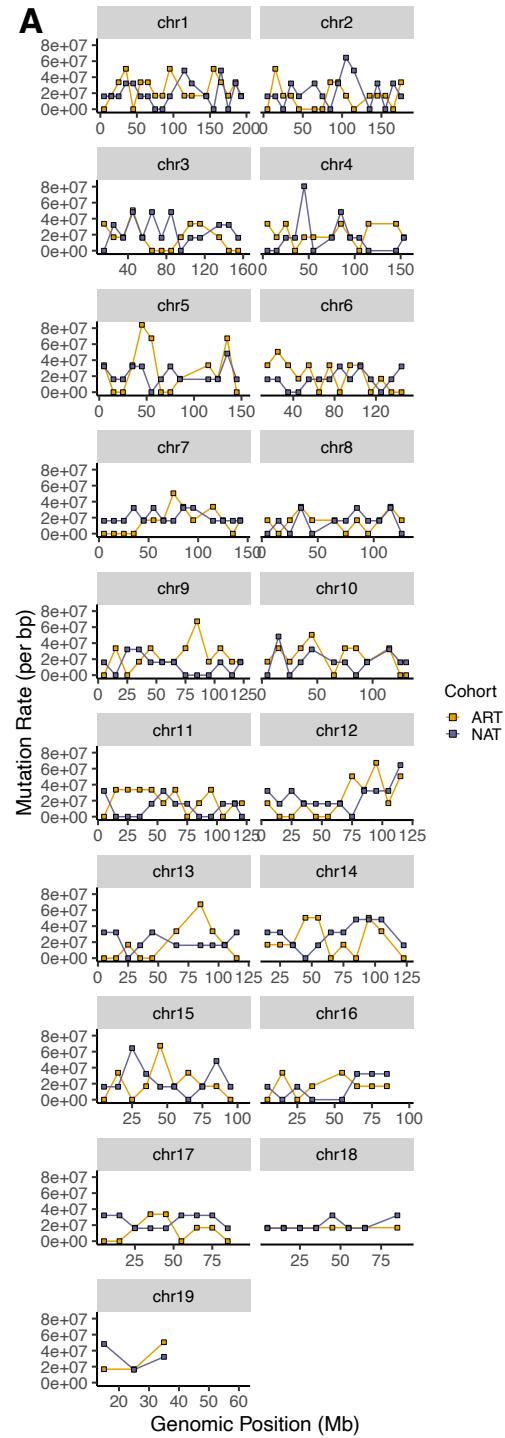

27  
 28 **Supplemental Figure 3.** Power to detect mutation rate differences under the analyzed  
 29 experimental conditions. We simulated dnSNVs in each G2 sample according to a Poisson  
 30 distribution, with rate parameter set to the number of expected germline mutations (genome size  
 31  $\times$  mutation rate in per base/per generation units). Simulations assume an average callable  
 32 genome size of 2.23 Gb, a baseline mutation rate of  $0.5 \times 10^{-8}$  per base per generation, and  
 33 impose read depth requirements of  $\geq 10$  total reads and  $\geq 3$  reads per allele. Binomial sampling  
 34 was used to capture the uncertainty associated with transmission of mutations arising in the G1  
 35 germline to the G2 generation. The mutation rate of the simulated natural cohort was held at the  
 36 simulated baseline rate, whereas the mutation rate of the simulated ART cohort was increased  
 37 by a fixed proportion across simulation sets (x-axis). The difference in mutation tallies among  
 38 the simulated natural and ART cohorts was assessed by a negative binomial generalized linear  
 39 mixed model of the form: dnSNV count  $\sim$  Cohort. We performed a total of 1000 simulation  
 40 replicates for each fractional increase in mutation rate in the ART cohort, retaining the cohort  
 41 term P-value from each replicate. Power was computed as the fraction of simulated datasets for  
 42 which  $P < 0.05$ . R code to reproduce simulations and this figure is available as supplemental  
 43 material.

44  
45 **Supplemental Figure 4.** Distribution of Mpileup variant annotations for dnSNVs in ART-  
46 (yellow) and naturally-conceived (purple) progeny. Annotations include: Base Quality Bias  
47 (BQB), Depth of Coverage (DP), Mapping Quality (MQ), Read Position Bias (RPB),  
48 Segregation-Based Score (SGB), and Variant Distance Bias (VDB). Distributions for each  
49 annotation metric are identical between the two groups (Kolmogorov-Smirnov Test,  $P > 0.05$ ).

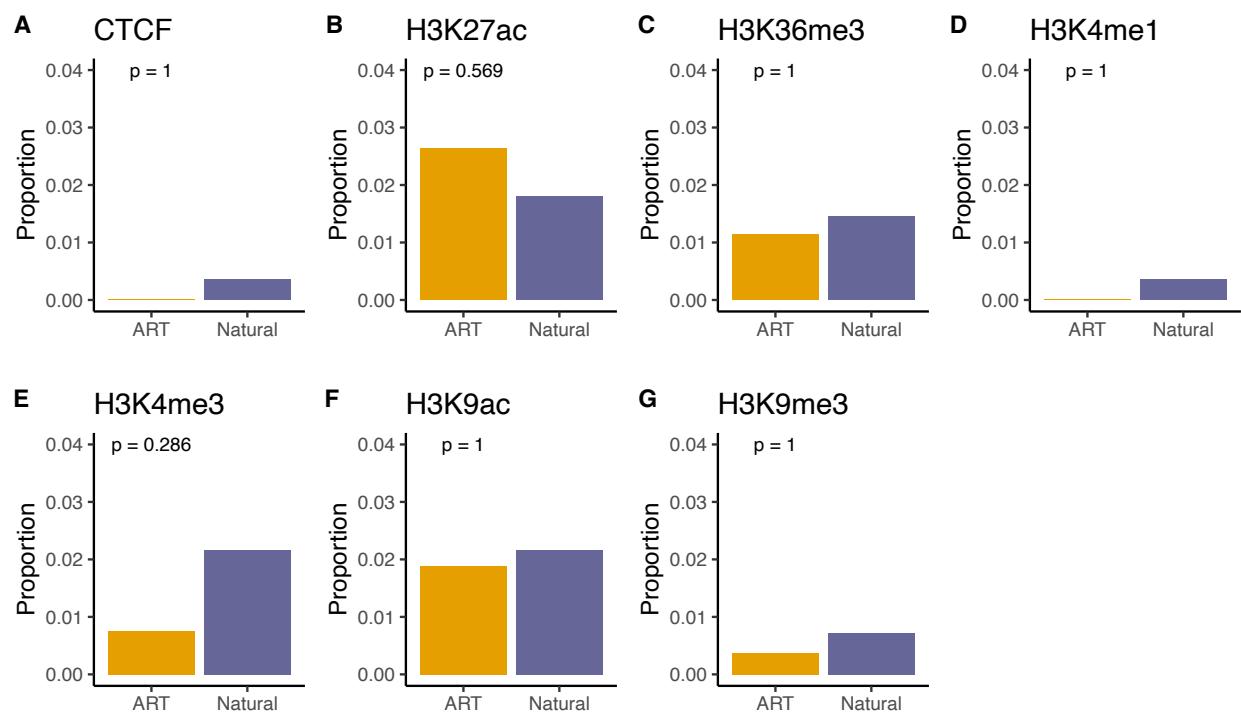

50  
 51 **Supplemental Figure 5.** Boxplots showing the median, interquartile range, and full range of  
 52 dnSNV rates per bp/generation across G2 samples. dnSNV calls were derived using only  
 53 sequencing data from (A) Seq1 and (B) Seq2.

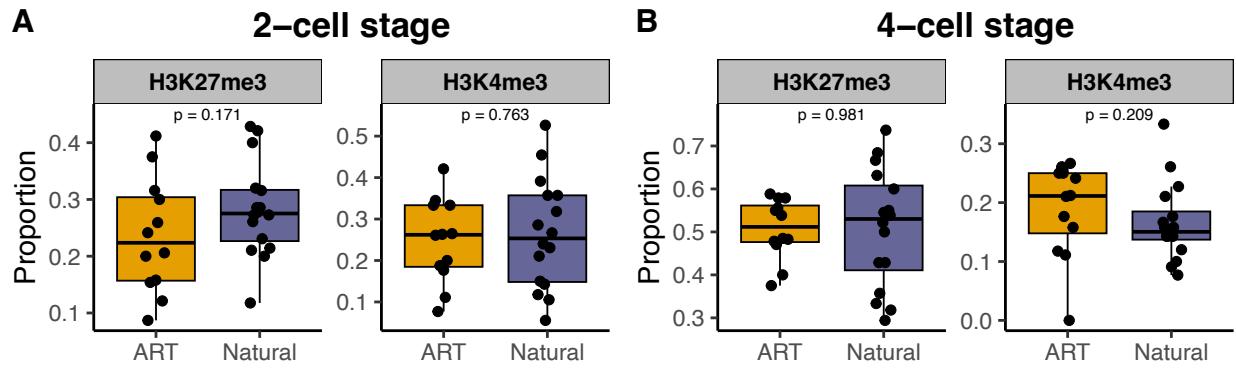

**Supplemental Figure 6.** (A) Genomic distribution of dnSNVs in ART-derived (orange) and natural-born (purple) cohorts. Mutation counts were aggregated in 10 Mb windows across the autosomal genome. (B) Violin plots depicting the distribution of GC content in 100 bp windows centered on dnSNVs identified in both cohorts. Embedded boxplots represent the interquartile range and median GC content. (C) Bar plot showing the percentage of dnSNVs in ART-and natural-born samples that overlap CpG islands. There is no cohort-level difference (Fisher's exact test,  $P = 0.6862$ ).

63

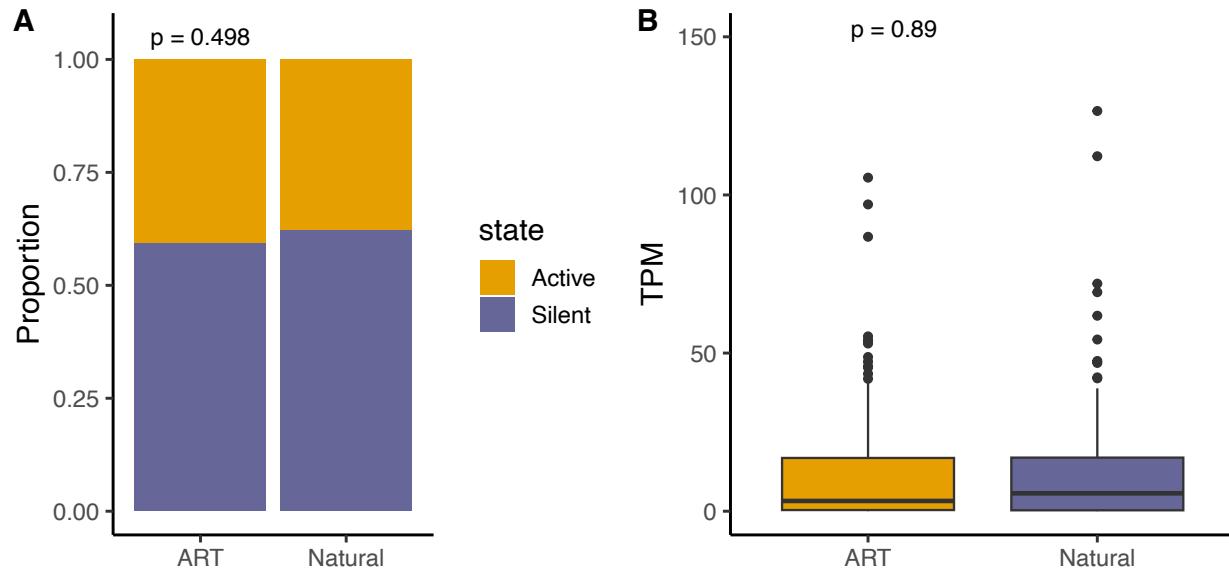

64

65 **Supplemental Figure 7.** Proportion of dnSNVs in ART- and naturally-born samples that overlap  
 66 ChIP-seq peaks associated with (A) CTCF binding or (B-G) various histone modifications in  
 67 mESCs. P-values were computed from Fisher's exact tests. ChIP-seq data are from the  
 68 Bruce4ES dataset released with the Mouse ENCODEproject (Stamatoyannopoulos *et al.* 2012).  
 69

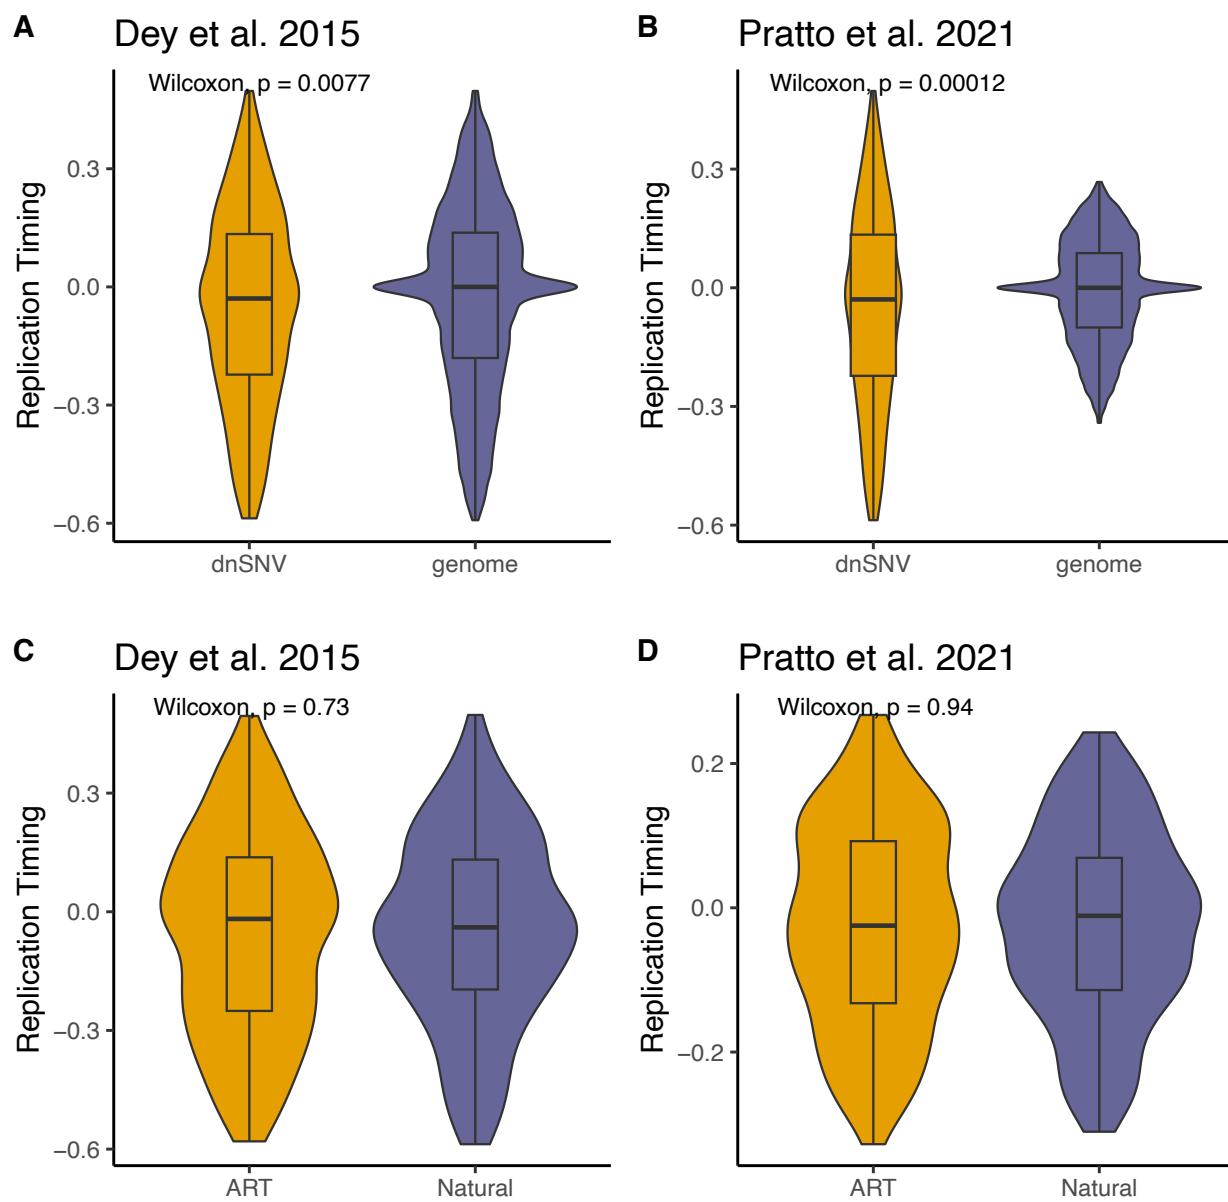

70  
71  
72  
73  
74  
75  
76

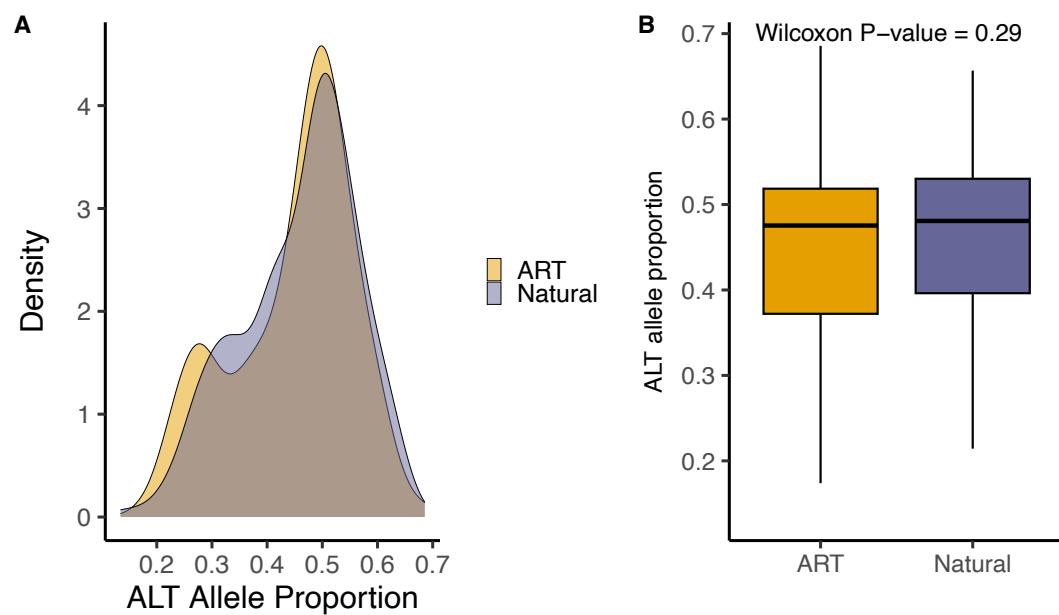

**Supplemental Figure 8.** Proportion of dnSNVs in ART- and naturally-born samples that overlap H3K27me3 and H3K4me3 ChIP-seq peaks in 2-cell stage (A) and 4-cell stage (B) mouse embryos. ChIP-seq data are from a published source (Liu et al. 2016). Significance was assessed by a two-tail Wilcoxon rank-sum test.

77  
78 **Supplemental Figure 9.** No difference in dnSNV distribution between ART- and natural-born  
79 progeny with respect to the transcriptional activity of neighboring genes in C57BL/6J mouse  
80 ESCs. dnSNVs were intersected with neighboring genes, with a 2.5kb allowance upstream of  
81 the gene start and downstream of the gene end. Both (A) the proportion of dnSNVs near genes  
82 that are expressed (Active) versus silenced (Silent) and (B) the overall transcript abundance of  
83 active genes expressed as transcripts per million (TPM) are indistinguishable between cohorts.  
84 Significance was assessed by a Fisher's exact test (A) or Wilcoxon rank-sum test (B).

**Supplemental Figure 10. Replication timing at dnSNVs.** Replication timing estimates were based on published Repli-seq datasets for mESCs (Dey et al. 2015; Pratto et al. 2021) and plotted as violin plots with inset boxplots indicating median (thick black line) and interquartile range (box height). Replication timing estimates are presented as  $\log_2$  early/late ratios, with lower values indicating regions that replicate later and more positive values consistent with earlier replication. Differences in replication timing between tested groups were evaluated using two-tailed Wilcoxon rank-sum tests. (A and B) Replication timing comparisons between aggregate dnSNVs discovered in both ART and natural-born mouse cohorts compared to genome-wide distribution of replication timing. dnSNVs are enriched in late replicating regions. (C and D) No difference in replication timing of dnSNVs in ART- versus natural-born mice.

**Supplemental Figure 11:** Distribution of ALT allele proportion by cohort. (A) Density plot showing the distribution of ALT allele proportions for dhSNVs in each cohort. (B) Boxplot comparing ALT allele proportions between cohorts.
